

Photovoltaic inverter anti-islanding test

Overview

IEC 62116, formally titled “Utility-Interconnected Photovoltaic Inverters – Test Procedure of Islanding Prevention Measures,” defines a standardized, repeatable test procedure to evaluate the anti-islanding performance of PV inverters. Islanding occurs when a distributed generator continues to power a location even though the main utility grid is shut down. This can be dangerous for utility workers and the equipment. This white paper provides a comprehensive overview of anti-islanding concepts, testing applications. Advanced Technology is the organization in SCE's Transmission and Distribution business unit and Engineering & Technical Services (E&TS) division that investigates advanced technologies and methodologies to support the utility's goals to provide safe, reliable and affordable energy while overcoming. Typically PV inverters perform the islanding detection function autonomously using one or more of a variety of methods. As PV and other DER systems are connected to the grid at increased penetration levels, island detection may become more challenging for two reasons: In islands containing many.
